## Abstract

Tabular expressions have been used in industry for many years to precisely document software in a readable notation. In this paper, we propose a fault-based testing technique that traces the propagation of faults from the expression in each cell of a tabular expression to the output of the program under test. The technique has been formalized in the form of abstract test case constraints also represented by tabular expressions, so that it can be easily applied and automated.

## 1. Introduction

In the past decades, many formal specification methods have been developed in an effort to document software specifications precisely and unambiguously, mostly by means of mathematical expressions. However, conventional mathematical expressions are too complex and difficult to read. To alleviate the problem, functional doc-

umentation using tabular expressions was proposed [6, 11]. They were proven to be useful and acceptable in industrial experiences with the US Navy's A-7 aircraft [3], a Bell Laboratories Service Evaluation system [4], the Darlington Nuclear Power Station [10], a Dell keyboard test program [13], and so on.

Two testing strategies were developed for tabular expressions: the partition strategy [9] and the interesting point selection strategy [1]. Acting as equivalence class testing and boundary value testing, respectively, they fulfill basic testing requirements. Test oracles in [12] can help verify testing results. To ensure a high quality of the software, however, we need more advanced strategies such as fault-based testing.

For the ease of discussions, we shall write tabular expressions interchangeably with their equivalent conventional mathematical expressions in this paper. Consider the following conventional definition of a simple function. We shall refer to  $x > 10$  and  $y > 5$  by the Boolean variables  $A$  and  $B$ , respectively. They are listed in bold and in parentheses.

$$f(x, y) = \begin{cases} x + y & \underline{x > 10} \wedge \underline{y > 5} \vee \underline{x \leq 10} \wedge \underline{y \leq 5} \\ & ( \mathbf{A} \wedge \mathbf{B} \vee \neg \mathbf{A} \wedge \neg \mathbf{B} ) \\ x - y & \underline{x \leq 10} \wedge \underline{y > 5} \vee \underline{x > 10} \wedge \underline{y \leq 5} \\ & ( \neg \mathbf{A} \wedge \mathbf{B} \vee \mathbf{A} \wedge \neg \mathbf{B} ) \end{cases}$$

Many fault-based testing strategies (such as [7, 8, 16]) have been proposed to generate test cases for Boolean expressions. Although these strategies can propagate

faults (such as missing  $A$  or the negation of  $A$ ) to affect the result of the expression  $A \wedge B \vee \neg A \wedge \neg B$ , more questions regarding fault propagation need to be addressed: (i) Can a change of the operator “ $>$ ” in  $x > 10$  affect  $A$ ? (ii) Can the result of  $A \wedge B \vee \neg A \wedge \neg B$  affect  $f(x, y)$ ? (iii) Can a fault in  $x + y$  be propagated to  $f(x, y)$ ? While there are studies (such as [5, 14]) addressing the first question, the other two have almost been ignored.

Fault-based testing in tabular expressions takes into account all the above-illustrated reflections as well as other features related to tabular expressions.

## 2. Tabular Expressions

A *tabular expression* is an indexed set of grids and each grid is an indexed set of expressions [6]. Fig. 1 is an example of a two-dimensional inverted table  $T$  consisting of three grids, such that the cardinality  $Card(T) = 3$  and the index sets  $IndexSet(T) = \{0, 1, 2\}$ ,  $IndexSet(T[1]) = IndexSet(T[2]) = \{0, 1, 2\}$ , and  $IndexSet(T[0]) = IndexSet(T[1]) \times IndexSet(T[2])$ .  $T[1]$  and  $T[0]$  are predicate grids while  $T[2]$  is an evaluation grid.  $T[1]$  and each row of  $T[0]$  are *proper*, that is, one and only one predicate expression can be *true* with respect to an assignment. If  $T[i][idx]$  ( $i \in IndexSet(T)$  and  $idx \in IndexSet(T[i])$ ) is taken as a Boolean variable, the expressions in bold are Boolean expressions.

A *specification* is a statement of all the properties required of a program; an *actual description* is a statement about actual attributes of a program. Accordingly, there are two kinds of table in this paper: a specification table (denoted by  $T_S$ ) and a description table (denoted by  $T_D$ ). For the readers’ convenience, in Fig. 1, the specification and a description share the same table with different expressions in  $T[1][0]$  and  $T[1][2]$ . The expressions in parentheses are for the description table.

## 3. Fault Propagation

*Fault propagation* spreads the faulty result in a problem to the output and causes a failure of the program. It can be revealed by an execution of the program [15] or an analysis of the source code [2].

Boolean expression-based strategies are successful in detecting faults in single Boolean expressions. For tabular expressions, however, additional issues need to be addressed. We discuss these issues based on the example in Fig. 1.

- (1)  $T[i][idx]$  represents an expression. Information is needed about the faults that may affect the expression, such as a change of “ $<$ ” in  $x < 3$  of  $T[1][2]$ , and a change of “ $x$ ” in  $x + y$  of  $T[2][0]$ .
- (2) The change in  $T[1][2]$  invokes a change in  $T[1][0]$  because  $T[1]$  is proper.
- (3) A change of result of a Boolean expression does not always entail a change of the output. Consider the second Boolean expression. Suppose  $x = 1$  and  $y = 0$ . Then, the expression is evaluated to *true* in  $T_S$  but *false* in  $T_D$ . Since the first Boolean expression is evaluated to *true* in  $T_D$ , the expressions in various evaluation grids are computed (namely,  $x - y$  and  $x + y$ ). However, since  $y$  is 0,  $x + y = x - y$ . Thus,  $x = 1, y = 0$  fails to propagate the fault.

### 3.1. Notation and Assumptions

Various programs may be written to implement a specification, with different kinds of fault. Hence, this paper considers only a subset of  $T_D$ . Further, we have the following assumptions: (i) All the programs are deterministic. (ii) Faults can either be in a predicate grid or in a cell of an evaluation grid. (iii) If an input is undefined in  $T_D$ , the output is out of the range of the programs. (iv) Since many techniques (such as fault-based testing [14] and mutation testing [5]) can be used for testing fault propagation from an expression in a cell to the result of the expression, test cases for any propagation exist.

Test cases are expressed in terms of test case constraints. In the sequel, “test case constraint” will be abbreviated to “constraint”. If no test data can be found, the constraint for the expression is *false*. Suppose  $idx$  is the index of an element in grid  $T[i]$ . Let  $C[i][idx]$  indicate the set of the constraints for the test data of expression  $T[i][idx]$  in assumption (iv). The following is the notation:

- (a)  $Card(C[i][idx])$  denotes the number of constraints in  $C[i][idx]$ .

$$\begin{array}{c}
Q(intx, inty) = \\
\begin{array}{ccc}
& & T[2] \\
& & \begin{array}{|c|c|c|}
\hline
x+y & x-y & x \times y \\
\hline
\end{array} \\
\begin{array}{|c|}
\hline
x > 3 \ (x < 3) \\
\hline
x = 3 \\
\hline
x < 3 \ (x > 3) \\
\hline
\end{array} & \begin{array}{|c|c|c|}
\hline
y < 6 & y = 6 & y > 6 \\
\hline
y < x & y > x & y = x \\
\hline
y < -x & y > -x & y = -x \\
\hline
\end{array} & \\
T[1] & & T[0]
\end{array} \\
Q(x, y) = \begin{cases}
x+y & (x > 3 \wedge y < 6) \vee (x = 3 \wedge y < x) \vee (x < 3 \wedge y < -x) \\
& (T[1][0] \wedge T[0][0, 0]) \vee (T[1][1] \wedge T[0][1, 0]) \vee (T[1][2] \wedge T[0][2, 0]) \\
x-y & (x > 3 \wedge y = 6) \vee (x = 3 \wedge y > x) \vee (x < 3 \wedge y > -x) \\
& (T[1][0] \wedge T[0][0, 1]) \vee (T[1][1] \wedge T[0][1, 1]) \vee (T[1][2] \wedge T[0][2, 1]) \\
x \times y & (x > 3 \wedge y > 6) \vee (x = 3 \wedge y = x) \vee (x < 3 \wedge y > -x) \\
& (T[1][0] \wedge T[0][0, 2]) \vee (T[1][1] \wedge T[0][1, 2]) \vee (T[1][2] \wedge T[0][2, 2])
\end{cases}
\end{array}$$

Figure 1: A specification (description) table.

- (b)  $C[i][idx][k]$  denotes the  $k$ th constraint in  $C[i][idx]$ .
- (c)  $T_S[i][idx][k]$  and  $T_D[i][idx][k]$ , respectively, denotes the expected result and actual result of the expression  $T_S[i][idx]$  with respect to a test case that satisfies  $C[i][idx][k]$ .
- (d)  $P[i][idx]$  denotes the set of constraints that propagate the faults in expression  $T_D[i][idx]$  to the output.
- (e) For any predicate grid  $T[i]$ ,  $C_T[i][idx][k]$  and  $C_F[i][idx][k]$  denote  $C[i][idx][k] \wedge T_S[i][idx]$  and  $C[i][idx][k] \wedge \neg T_S[i][idx]$ , respectively.
- (f)  $P_T[i][idx][k]$  and  $P_F[i][idx][k]$  denote the set of constraints to propagate faults in expression  $T_D[i][idx]$  when the test cases satisfy  $C_T[i][idx][k]$  or  $C_F[i][idx][k]$ , respectively. They denote  $\emptyset$  when  $C_T[i][idx][k]$  or  $C_F[i][idx][k]$  is *false*.
- (g)  $P[i][idx][k]$  denotes the set of constraints to propagate faults in expression  $T_D[i][idx]$  when the test cases satisfy  $C[i][idx][k]$ .
- (h)  $\nabla$  is defined by

$$S_1 \nabla S_2 = \begin{cases} S_1 \cup S_2 & S_1 = \emptyset \vee S_2 = \emptyset \\ S_1 \text{ or } S_2 & S_1 \neq \emptyset \wedge S_2 \neq \emptyset \end{cases}$$

### 3.2. Test Case Generation

To make the expressions more compact, we use  $\bigvee_{j=1}^h v[j]$  to denote  $v[1] \vee v[2] \vee \dots \vee v[h]$ ,  $\bigwedge_{j=1}^h v[j]$  to denote  $v[1] \wedge v[2] \wedge \dots \wedge v[h]$ , and  $d_i$  to denote  $\text{Card}(T[i])$  ( $1 \leq i \leq \text{Card}(T) - 1$ ). The output of an inverted table can be written in the following form:

$$O = T[n][j_n] \bigvee_{j_1=0}^{d_1-1} \dots \bigvee_{j_{n-1}=0}^{d_{n-1}-1} \left( T[0][j_1, \dots, j_n] \wedge \left( \bigwedge_{i=1}^{n-1} T[i][j_i] \right) \right) \quad (1)$$

for  $0 \leq j_n \leq d_n - 1$ , where  $n = \text{Card}(T) - 1$ . It means that the output is  $T[n][j_n]$  if the conditional expression subsequent to this output is satisfied. Moreover, an inverted table has the following characteristics:

- For  $1 \leq i \leq n - 1$ ,  $\bigvee_{j=0}^{d_i-1} T[i][j] = \text{true}$ .
- For  $1 \leq i \leq n - 1$  and  $0 \leq j, j' \leq d_i - 1$  such that  $j \neq j'$ ,  $T[i][j] \wedge T[i][j'] = \text{false}$ .
- Given any input, if  $\bigwedge_{i=1}^{n-1} T[i][j_i] = \text{true}$ ,  $\bigvee_{j_n=0}^{d_n-1} T[0][j_1, \dots, j_{n-1}, j_n] = \text{true}$  and, for  $0 \leq j_n, j'_n \leq$

$d_n - 1$  such that  $j_n \neq j'_n$ ,  $T[0][j_1, \dots, j_{n-1}, j_n] \wedge T[0][j_1, \dots, j_{n-1}, j'_n] = false$ .

Faults may be in  $T[i]$  ( $1 \leq i \leq n-1$ ),  $T[n]$ , or  $T[0]$ . Thus, we have three cases:

**(1) The faults are in evaluation expressions in  $T[n]$ .**

Suppose that there are faults in  $T[n][j]$  ( $0 \leq j \leq d_n - 1$ ). To propagate the faults, the evaluation expression must be evaluated with respect to an input, that is,  $\bigvee_{j_1=0}^{d_1-1} \dots \bigvee_{j_{n-1}=0}^{d_{n-1}-1} \left( T[0][j_1, \dots, j_{n-1}, j] \wedge \left( \bigwedge_{i=1}^{n-1} T[i][j_i] \right) \right)$  must be *true*. Hence, for  $0 \leq j \leq d_n - 1$ ,  $P[n][j] = \left\{ C[n][j][k] \wedge \left( \bigvee_{j_1=0}^{d_1-1} \dots \bigvee_{j_{n-1}=0}^{d_{n-1}-1} \left( T[0][j_1, \dots, j_{n-1}, j] \wedge \left( \bigwedge_{i=1}^{n-1} T[i][j_i] \right) \right) \mid 1 \leq k \leq Card(C[n][j]) \right\}$ .

**(2) The faults are in the predicate expressions in  $T[i]$  ( $1 \leq i \leq n-1$ ).**

The output function in (1) can be rewritten as

$$O = T[n][j_n] \quad \bigvee_{j_i=0}^{d_i-1} \left( T[i][j_i] \wedge Q(i, j_i, j_n) \right) \quad (2)$$

where  $Q(i, j_i, j_n) = \bigvee_{j_1=0}^{d_1-1} \dots \bigvee_{j_{i-1}=0}^{d_{i-1}-1} \bigvee_{j_{i+1}=0}^{d_{i+1}-1} \dots \bigvee_{j_{n-1}=0}^{d_{n-1}-1} \left( T[0][j_1, \dots, j_i, \dots, j_{n-1}, j_n] \wedge \left( \bigwedge_{l=1}^{i-1} T[l][j_l] \right) \wedge \left( \bigwedge_{l=i+1}^{n-1} T[l][j_l] \right) \right)$ . If  $n = 2$ , we have  $i = 1$  (since  $1 \leq i \leq n-1$ ) and  $Q(i, j_i, j_n) = T[0][j_1, j_2]$ . If  $n > 2$ ,  $i$  can be any value that satisfies  $1 \leq i \leq n-1$ .

Suppose that a test case satisfies  $C[i][j][k]$ . There are two possibilities:

(a) *The test case satisfies  $C_T[i][j][k]$ .*

Obviously, it evaluates  $T[i][j]$  to *true*, that is,  $T_S[i][j][k] = true$  and  $T_D[i][j][k] = false$ . When  $T_S[i][j][k]$  is *true*,  $T_S[i][j'][k] = false$  for  $0 \leq j' \leq d_i - 1$  such that  $j' \neq j$ . The output in (2) can be simplified to

$$O = T[n][j_n] \quad Q(i, j, j_n)$$

There are two sub-cases:

- For all  $j' \neq j$  such that  $0 \leq j' \leq d_i - 1$ ,  $T_D[i][j'][k] = false$ .

In this case, for any  $j_i$  such that  $0 \leq j_i \leq d_i - 1$ , we have  $T_D[i][j_i] = false$ .

Thus, no matter what  $j_n$  is,  $\bigvee_{j_i=0}^{d_i-1} \left( T_D[i][j_i] \wedge \right.$

$\left. Q(i, j_i, j_n) \right)$  is always *false*. Such a test case is undefined in the implementation. According to assumption (iii) in Section 3.1, the actual output is out of range and, therefore, different from any expected output under the predicate  $T_S[i][j]$ . Hence, for  $1 \leq i \leq n-1$  and  $0 \leq j \leq d_i - 1$ ,  $P_T^1[i][j][k] = \left\{ C_T[i][j][k] \wedge \left( \bigvee_{j_n=0}^{d_n-1} Q(i, j, j_n) \right) \right\}$ . Since  $\bigvee_{j_n=0}^{d_n-1} Q(i, j, j_n) = true$ , we have  $P_T^1[i][j][k] = \{ C_T[i][j][k] \}$ .

- $T_D[i][j'][k] = true$  for some  $j' \neq j$  such that  $0 \leq j' \leq d_i - 1$ .

Since the test case evaluates  $T_D[i][j']$  to *true*, the output function for  $T_D$  is written as

$$O = T[n][j_n] \quad Q(i, j', j_n)$$

Therefore,  $P_T^2[i][j][k] = \left\{ C_T[i][j][k] \wedge \left( \bigvee_{j_n=0}^{d_n-1} \left( Q(i, j, j_n) \wedge \neg Q(i, j', j_n) \wedge \left( \bigvee_{j'_n=0, j'_n \neq j_n}^{d_n-1} \left( Q(i, j', j'_n) \rightarrow T[n][j'_n] \neq T[n][j_n] \right) \right) \right) \mid 0 \leq j' \leq d_i - 1 \wedge j \neq j' \right\}$ .

Thus, we can determine  $P_T[i][j][k] = P_T^1[i][j][k] \cup P_T^2[i][j][k]$ .

(b) *The test case satisfies  $C_F[i][j][k]$ .*

It evaluates  $T_S[i][j]$  to *false* and  $T_D[i][j]$  to *true*.  $T_S[i][j'][k] = true$  for some  $j' \neq j$  such that  $0 \leq j' \leq d_i - 1$ . The analysis is similar to the second case in (a). The set of constraints is given by  $P_F[i][j][k] = \left\{ C_F[i][j][k] \wedge T_S[i][j'] \wedge \left( \bigvee_{j_n=0}^{d_n-1} \left( Q(i, j', j_n) \wedge \neg Q(i, j, j_n) \wedge \left( \bigvee_{j'_n=0, j'_n \neq j_n}^{d_n-1} \left( Q(i, j, j'_n) \rightarrow T[n][j'_n] \neq T[n][j_n] \right) \right) \right) \mid 0 \leq \right.$

$$j' \leq d_i - 1 \wedge j \neq j' \}.$$

Thus, we can determine  $P[i][j][k] = P_T[i][j][k] \vee P_F[i][j][k]$  and hence  $P[i][j] = \{p \in P[i][j][k] \mid 0 \leq k \leq \text{Card}(C[i][j]) - 1\}$ .

### (3) The faults are in the predicate expressions in $T[0]$ .

Suppose that a test case satisfies  $C[0][j_1, \dots, j_{n-1}, j][k]$ . Similarly to the above, there are two possibilities.

(a) *The test case satisfies  $C_T[0][j_1, \dots, j_{n-1}, j][k]$ .*

Since  $T_S[0][j_1, \dots, j_{n-1}, j][k] = \text{true}$ , we have  $T_D[0][j_1, \dots, j_{n-1}, j][k] = \text{false}$ . There are two sub-cases:

- For all  $j' \neq j$  such that  $0 \leq j' \leq d_n - 1$ ,  $T_D[0][j_1, \dots, j_{n-1}, j'][k] = \text{false}$ .

For any  $j_n$  such that  $0 \leq j_n \leq d_n - 1$ , we have  $T_D[0][j_1, \dots, j_{n-1}, j_n][k] = \text{false}$ . Such a test case is undefined in the implementation. To propagate faults,  $T_D[0][j_1, \dots, j_{n-1}, j]$  must be evaluated. Hence,  $P_T^1[0][j_1, \dots, j_{n-1}, j][k] = \{C_T[0][j_1, \dots, j_{n-1}, j][k] \wedge (\bigwedge_{i=1}^{n-1} T[i][j_i])\}$ .

- $T_D[0][j_1, \dots, j_{n-1}, j'][k] = \text{true}$  for some  $j' \neq j$  such that  $0 \leq j' \leq d_n - 1$ .

Since  $T_D[0][j_1, \dots, j_{n-1}, j']$  corresponds to the output  $T[n][j']$ , we must have  $T[n][j'] \neq T[n][j]$  to make the output different. Therefore,  $P_T^2[0][j_1, \dots, j_{n-1}, j][k] = \{C_T[0][j_1, \dots, j_{n-1}, j][k] \wedge (\bigwedge_{i=1}^{n-1} T[i][j_i]) \wedge T[n][j] \neq T[n][j'] \mid 0 \leq j' \leq d_n - 1 \wedge j' \neq j\}$ .

Hence, we can determine  $P_T[0][j_1, \dots, j_{n-1}, j][k] = P_T^1[0][j_1, \dots, j_{n-1}, j][k] \cup P_T^2[0][j_1, \dots, j_{n-1}, j][k]$ .

(b) *The test case satisfies  $C_F[0][j_1, \dots, j_{n-1}, j][k]$ .*

$T_S[0][j_1, \dots, j_{n-1}, j'][k]$  is evaluated to *true* for some  $j'$  such that  $0 \leq j' \leq d_n - 1$ . Since  $T_D[0][j_1, \dots, j_{n-1}, j][k]$  is *true*, they correspond to  $T[n][j']$  and  $T[n][j]$ , respectively.

Hence,  $P_F[0][j_1, \dots, j_{n-1}, j][k] = \{C_F[0][j_1, \dots, j_{n-1}, j][k] \wedge T_S[0][j_1, \dots, j_{n-1}, j'] \wedge (\bigwedge_{i=1}^{n-1} T[i][j_i]) \wedge T[n][j] \neq T[n][j'] \mid 0 \leq j' \leq d_n - 1 \wedge j' \neq j\}$ .

Thus,  $P[0][j_1, \dots, j_{n-1}, j] = \{p \in P[0][j_1, \dots, j_{n-1}, j][k] \mid 0 \leq k \leq \text{Card}(C[0][j_1, \dots, j_{n-1}, j])\}$ , where  $P[0][j_1, \dots, j_{n-1}, j][k] = P_T[0][j_1, \dots, j_{n-1}, j][k] \vee P_F[0][j_1, \dots, j_{n-1}, j][k]$ .

Application of the method is simple because all the formulas have been given. Testers need only copy the actual expressions from the tables to the formulas. The constraints for the first step of the propagation can be obtained by applying the *MIST* technique in [2]. The subsequent process can be easily automated.

## 4. Conclusion and Future Work

We have shown that fault propagation can be taken into account in tabular expression-based specifications. The testing method proposed in this paper propagates not only faults in predicate expressions but also faults in evaluation expressions. The formulae in our method make test case generation easier in two ways: (a) they facilitate the implementation of the tool that automates the method; and (b) if testers generate test data manually, they only need to replace the notation in the formulae with actual expressions in the specification table.

Although we have illustrated our method through inverted tables, we can also use it in other types of table. Our SQL laboratory has been developing the tools to support this method. We have also designed the experiments to further compare this method with other selected testing strategies. On the other hand, we have noted that some generated constraints are equivalent because of the completeness of the grids in the table specification. Hence, we are studying the method to generate test case constraints for only part of the table but covering the whole.
