Classless Java
Interface-Based Programming for the Masses

Abstract
This paper introduces interface-based object-oriented programming (IB). Unlike class-based OO programming (CB), in IB there is no need for classes. To support state, IB uses abstract state operations, such as getters, setters or clone-like methods. This new way to deal with state allows flexibility not typically available in CB. In IB state (including mutable state) can be type-refined in subtypes. The combination of a purely IB style of programming and type-refinement enables powerful idioms using multiple inheritance and state. To introduce IB to programmers we created Classless Java: an embedding of IB directly into Java. Classless Java uses annotation processing for code generation, and relies on new features of Java 8 for interfaces. The code generation techniques used in Classless Java have interesting properties, including guarantees that no type errors occur in generated code and good integration with IDE’s. We illustrate the usefulness of IB and Classless Java through various examples and case studies.

1. Introduction
Object-oriented languages strive to offer great code reuse. They couple flexibility and rigour, expressive power and modular reasoning. Two main ideas emerged to this end: prototype-based (PB) [21] and class-based languages such as Java, C# or Scala. In prototype-based languages objects inherit from other objects. Thus objects own both behaviour and state (and objects are all you have). In class-based languages an object is an instance of a specific class, and classes inherit from other classes. Objects own state, while classes contain behaviour and the structure of the state.

This paper presents a third alternative: the concept of interface-based object-oriented programming languages (IB), where objects implement interfaces directly. In IB interfaces own the implementation for the behaviour, which is structurally defined in their interface. Programmers do not define objects directly, but delegate the task to object interfaces, whose role is similar to non-abstract classes in class-based object-oriented programming languages (CB). Objects are instantiated by static factory methods in object interfaces.

A key challenge in IB lies in how to model state, which is fundamental to have stateful objects. All abstract operations in an object interface are interpreted as abstract state operations. The abstract state operations include various common utility methods (such as getters and setters, or clone-like methods). Objects are only responsible to define the ultimate behaviour of a method. Anything related to state is completely contained in the instances and does not leak into the inheritance logic. In CB, the structure of the state is fixed and can be only grown by inheritance. In contrast, in IB the state is never fixed, and methods such as abstract setters and getters can always receive an explicit implementation down in the inheritance chain, improving modularity and flexibility. That is, the concept of abstract state is more fluid.

Object interfaces provide support for automatic type-refinement. In contrast, in CB special care and verbose explicit type-refinement are required to produce code that deals with subtyping adequately.

We believe that such verbosity hindered and slowed down the discovery of useful programming patterns involving type-refinement. A recently discovered solution [23] to the Expression Problem [22] in Java-like languages, shows how easy it is to solve the problem using only type-refinement. However it took nearly 20 years since the formulation of the problem for that solution to be presented in the literature. In IB, due to its emphasis on type-refinement, that solution should have been much more obvious.

One advantage of abstract state operations and type-refinement is that it allows a new approach to type-safe covariant mutable state. That is, in IB, it is possible to type-refine mutable “fields” in subtypes. This is typically forbidden in CB: it is widely known that naive type-refinement of mutable fields is not type-safe. While covariant refinement of mutable fields is supported by some type systems [5, 6, 8, 17], this requires significant complexity and restrictions to ensure that all uses of covariant state are indeed type-safe.

Another advantage of IB is its support for multiple inheritance. The literature is rich on how easy it is to combine multiple sources of pure behaviour, using mechanisms such as traits [19]. In Java multiple interface inheritance has been
supported since inception, and in Java 8 default methods [10] bring some of the advantages of traits into Java. In contrast, the literature [4, 13, 18] is also rich on how hard it is to modularly combine multiple sources of behaviour and state with multiple implementation inheritance of classes. In IB there is only multiple interface inheritance, yet programmers can still use state via abstract state operations. IB enables powerful idioms using multiple inheritance and state.

IB could be explained by defining a novel language, with new syntax and semantics. However, this would have a steep learning curve. We take a different approach instead. For the sake of providing a more accessible explanation, we will embed our ideas directly into Java. Our IB embedding relies on the new features of Java 8: interface static methods and default methods, which allow interfaces to have method implementations. In the context of Java, what we propose is a programming style, where we never use classes (more precisely, we never use the class keyword). We call this restricted version of Java Classless Java.

Using Java annotation processors, we produce an implementation of Classless Java, which allows us to stick to pure Java 8. By annotating the interfaces that represent object interfaces with @Obj, code for interface instantiation and type refinement can be automatically generated. Such code should not be needed in the first place in a real IB language, and the annotation processor allows us to transparently hide it from Java programmers. The implementation works by performing AST rewriting, allowing most existing Java tools (such as IDEs) to work out-of-the-box with our implementation. Moreover, the implementation blends Java’s conventional CB style and IB smoothly. As a result, we experiment object interfaces with several interesting Java programs and conduct various case studies. Finally, we also discuss the behaviour of our @Obj annotation and its properties.

While the Java embedding has obvious advantages from the practical point-of-view, it also imposes some limitations that a new IB language would not have. In particular, supporting proper encapsulation is difficult in Java due to limitations of Java interfaces. In particular in Java interfaces the visibility of all methods is public. Thus modelling private state is difficult in current Java 8. However, using existing design patterns [2] we can emulate hiding methods from interfaces. Furthermore Java 9 will allow private methods on interfaces [20], greatly improving the support for encapsulation.

In summary, the contributions of this paper are:

• **IB and Object Interfaces**: which enable powerful programming idioms using multiple-inheritance, type-refinement and abstract state operations.

• **Classless Java**: a practical realization of IB in Java. Classless Java is implemented using annotation processing, allowing most tools to work transparently with our approach. We provide the formal semantics here ¹. Existing Java projects can use our approach and still be backward compatible with their clients, in a way that is specified by our safety properties.

• **Type-safe covariant mutable state**: we show how the combination of abstract state operations and type-refinement enables a form of mutable state that can be covariantly refined in a type-safe way.

• **Applications and case studies**: we illustrate the usefulness of IB through various examples and case studies.

2. A Running Example: Animals

This section illustrates how our programming style, supported by @obj, enables powerful programming idioms based on multiple inheritance and type refinements. We propose a standard example: Animals with a 2-dimensional Point2D representing their location, subtypes Horses, Birds, and Pegasus. Birds can fly, thus their locations need to be 3-dimensional Point3D (field type refinement). We model Pegasus (a well-known creature in Greek mythology) as a kind of Animal with the skills of both Horses and Birds (multiple inheritance). A simple class diagram illustrating the basic system is given on the left side of Figure 1.²

2.1 Simple Multiple Inheritance with Default Methods

Before modelling the complete animal system, we start with a simple version without locations. This version serves the purpose of illustrating how Java 8 default methods can already model simple forms of multiple inheritance. Horse and Bird are subtypes of Animal, with methods run() and fly(), respectively. Pegasus can not only run but also fly! This is the place where “multiple inheritance” is needed, because Pegasus needs to obtain fly and run functionality from both Horse and Bird. A first attempt to model the animal system is given on the right side of Figure 1. Note that the implementations of the methods run and fly are defined inside interfaces, using default methods. Moreover, because interfaces support multiple interface inheritance, the interface for Pegasus can inherit behaviour from both Horse and Bird. Although Java interfaces do not allow instance fields, no form of state is needed so far to model the animal system.

**Instantiation** To use Horse, Bird and Pegasus, some objects must be created first. A first problem with using interfaces to model the animal system is simply that interfaces cannot be directly instantiated. Classes, such as:

```java
class HorseImpl implements Horse {
    ...
}
class BirdImpl implements Bird {
    ...
}
class PegasusImpl implements Pegasus {
    ...
}
```

are needed for instantiation. Now a Pegasus animal can be created using the class constructor:

```java
Pegasus p = new PegasusImpl();
```

There are some annoyances here. Firstly, the sole purpose of the classes is to provide a way to instantiate objects. Although

¹ See Formal semantics for Classless Java is provided in Section A

² Some research argues in favor of using subtyping for modeling taxonomies, other research argues against this practice, we do not wish to take sides in this argument, but to provide an engaging example.
(in this case) it takes only one line of code to provide each of those classes, this code is essentially boilerplate code, which does not add behavior to the system. Secondly, the namespace gets filled with three additional types. For example, both Horse and HorseImpl are needed; Horse is needed because it needs to be an interface so that Pegasus can use multiple inheritance; and HorseImpl is needed to provide object instantiation. Note that, for this very simple animal system, plain Java 8 anonymous classes can be used to avoid these problems. We could have simply instantiated Pegasus using: Pegasus p = new Pegasus(); // anonymous class However, as we shall see, once the system gets a little more complicated, the code for instantiation quickly becomes more complex and verbose (even with anonymous classes).

2.2 Object Interfaces and Instantiation

To model the animal system with object interfaces all that a user needs to do is to add an @Obj annotation to the Horse, Bird, and Pegasus interfaces:

```java
@Obj interface Horse extends Animal {
  default void run() { out.println("running!"); } // annotated method
}
@Obj interface Bird extends Animal {
  default void fly() { out.println("flying!"); } // annotated method
}
@Obj interface Pegasus extends Horse, Bird {}
```

The effect of the annotations is that a static factory method called of is automatically added to the interfaces. With the @Obj interface Pegasus is instantiated as follows:

```java
Pegasus p = Pegasus.of();
```

The of method provides an alternative to a constructor, which is automatically added to the interfaces. With the @Obj annotation the code corresponding to the Pegasus interface after the @Obj annotation is processed:

```java
interface Pegasus extends Horse, Bird {
  static Pegasus of() { return new Pegasus(); } // static factory method
}
```

Note that the generated code is transparent to a user, who only sees the original code with the @Obj annotation. Compared to the pure Java solution in Section 2.1, the solution using object interfaces has the advantage of providing a direct mechanism for object instantiation, which avoids adding boilerplate classes to the namespace.

2.3 Object Interfaces with State

The animal system modeled so far is a simplified version of the system presented in the left-side of Figure 1. The example is still not sufficient to appreciate the advantages of IB programming. Now we model the complete animal system where an Animal includes a location representing its position in space. We use 2D points to keep track of locations using coordinates.

**Point2D: simple immutable data with fields**

Here we will illustrate how points are modelled with interfaces. In IB state is accessed and manipulated using abstract methods. The usual approach to model points in Java is to use a class with fields for the coordinates. In Classless Java interfaces are used instead:

```java
interface Point2D {
  int x();
  int y();
}
```

The encoding over pure Java is now inconvenient: creating a new point object is cumbersome, even with anonymous classes:

```java
Point2D p = new Point2D() {
  public int x() { return 4; }
  public int y() { return 2; }
}
```

However this cumbersome syntax is not required for every object allocation. As programmers do, for ease or reuse, the boring repetitive code can be encapsulated in a method. A generalization of the of static factory method is appropriate:

```java
interface Point2D {
  int x();
  int y();
  static Point2D of(int x, int y) {
    return new Point2D() {
      public int x(){return x;}
      public int y(){return y;}
    };
  }
}
```

**Point2D with object interfaces**

This obvious “constructor” code can be generated by the @Obj annotation. By annotating the interface Point2D, a variation of the shown static method of will be generated, mimicking the functionality of a simple-minded constructor. @Obj first looks at the abstract methods and detects what the fields are, then generates an of method with one parameter for each of them. That is, we can just write:

```java
@Obj interface Point2D {
  int x();
  int y();
}
```

More precisely, a field or factory parameter is generated for every abstract method that takes no parameters. An example of using Point2D is:

```java
Point2D p = Point2D.of(42,myPoint.y());
```

where we return a new point, using 42 as x-coordinate, and taking all the other information (only y in this case) from another point.
with-methods in object interfaces The pattern of creating a new object by reusing most information from an old object is very common when programming with immutable data-structures. As such, it is supported by @Obj as with-methods. For example:

```java
@Obj interface Point2D {
    int x(); int y(); // getters
    // with-methods
    Point2D withX(int val);
    Point2D withY(int val);
}
```

Using with-methods, the point p can also be created by:

```java
Point2D p = myPoint.withX(42);
```

If there is a large number of fields, with-methods will save programmers from writing large amounts of tedious code that simply copies field values. Moreover, if the programmer wants a different implementation, he may provide an alternative implementation using default methods. For example:

```java
@Obj interface Point2D {
    int x(); int y();
    default Point2D withX(int val){ /*myCode*/ }
    default Point2D withY(int val); }
```

is expanded into

```java
interface Point2D {
    int x(); int y();
    default Point2D withX(int val){ /*myCode*/ }
    default Point2D withY(int val); }
```

Only code for methods needing implementation is generated. Thus, programmers can easily customize the behaviour for their special needs. Also, since @Obj interfaces offer the of factory method, only interfaces where all the abstract methods can be synthesized can be object interfaces. A non @Obj interface is like an abstract class in Java.

Animal and Horse: simple mutable data with fields 2D points are mathematical entities, thus we choose an immutable data structure to model them. However animals are real world entities, and when an animal moves, it is the same animal with a different location. We model this with mutable state.

```java
interface Animal {
    Point2D location();
    void location(Point2D val); }
```

Here we declare an abstract getter and setter for the mutable “field” location. Without the @Obj annotation, there is no convenient way to instantiate Animal. For Horse, the @Obj annotation is used and an implementation of run() is defined using a default method. The implementation of run() further illustrates the convenience of with-methods:

```java
@Obj interface Horse extends Animal {
    default void run()
    { location(location().withX(location().x() + 20)); }
```

Creating and using Horse is quite simple:

```java
Point2D p = Point2D.of(0, 0);
Horse horse = Horse.of(p);
horse.location(p.withX(42));
```

Note how the of, withX and location methods (all generated automatically) provide a basic interface for dealing with animals.

In summary, dealing with state (mutable or not) in object interfaces relies on a notion of abstract state, and state is not directly available to programmers. Instead programmers use methods, called abstract state operations, to interact with state.

2.4 Object Interfaces and Subtyping

Birds are Animals, but while Animals only need 2D locations, Birds need 3D locations. Therefore when the Bird interface extends the Animal interface, the notion of points needs to be refined. Such kind of refinement is challenging in typical class-based approaches. Fortunately, with object interfaces, we are able to provide a simple and effective solution.

 Unsatisfactory class-based solutions to field type refinement In Java if we want to define an animal class with a field we have a set of unsatisfactory options in front of us:

- Define a Point3D field in Animal: this is bad since all animals would require more than needed. Also it requires adapting the old code to accommodate for new evolutions.
- Define a Point2D field in Animal and define an extra int z field in Bird. This solution is very ad-hoc, requiring to basically duplicate the difference between Point2D and Point3D inside Bird. The most dramatic criticism is that it would not scale to a scenario when Bird and Point3D are from different programmers.
- Redefine getters and setters in Bird, always put Point3D objects in the field and cast the value out of the Point2D field to Point3D when implementing the overridden getter. This solution scales to the multiple programmers approach, but requires ugly casts and can be implemented in a wrong way leading to bugs.

We may be tempted to assume that a language extension is needed. Instead, the restriction of (object) interfaces to have no fields enlightens us that another approach is possible; often in programming languages “freedom is slavery”.

Field type refinement with object interfaces Object interfaces address the challenge of type-refinement as follows:

- by covariant method overriding, the return type of location() is refined to Point3D;
- by overloading, a new setter for location is defined with a more precise type;
- a default setter implementation with the old signature is provided.

Thus, with object interfaces, the code for the Bird interface is:

```java
@Obj interface Bird extends Animal {
    Point3D location(); void location(Point3D val);
    location(location().withX(location().x() + 20));
} }
default void location(Point2D val) { 
    location(location().with(val));
}
default void fly() { 
    location(location().withX( 
        location().x() + 40));
}

from the type perspective, the key is the covariant method 
overriding of location(). However, from the semantics 
perspective the key is the implementation for the setter 
with the old signature (location(Point2D)). The key to the 
setter implementation is a new type of with method, called a 
(functional) property updater.

Point3D and property updaters The Point3D interface is 
defined as follows:
@Obj interface Point3D extends Point2D {
    int z();
    Point3D withZ(int z);
    Point3D with(Point2D val); }
Point3D includes a with method, taking a Point2D as an 
argument. Other wither methods (such as withX) functionally 
update a field one at a time. This can be inefficient, and 
sometimes hard to maintain. Often we want to update multiple 
fields simultaneously, for example using another object as 
source. Following this idea, the method with(Point2D) is an 
elementary example of a (functional) property updater: it takes a certain 
type of object and returns a copy of the current object where all 
the fields that match fields in the parameter object are 
updated to the corresponding value in the parameter. The idea 
is that the result should be like this, but modified to be as 
similar as possible to the parameter.

With the new with method we may use the information for 
z already stored in the object to forge an appropriate Point3D 
to store. Note how all the information about what fields sit 
in Point3D and Point2D is properly encapsulated in the with 
method, and is transparent to the implementer of Bird.

Property updaters never break class invariants, since they 
internally call operations that were already deemed safe by 
the programmer. For example a list object would not offer a 
setter for its size field (which should be kept hidden), thus a 
property updater would not attempt to set it.

Generated boilerplate Just to give a feeling of how much 
mechanical code @Obj is generating, we show the generated 
code for the Point3D in Figure 2. Writing such code by hand 
is error-prone. For example a distracted programmer may 
swap the arguments of calls to Point3D.of. Note how with-
methods are automatically refined in their return types, so 
that code like:
Point3D p = Point3D.of(1,2,3); p = p.withX(42);
will be accepted. If the programmer wishes to suppress this 
behavior and keep the signature as it was, it is sufficient to 
redefine the with- methods in the new interface repeating the 
old signature. Again, the philosophy is that if the programmer 
provides something directly, @Obj does not touch it. The cast 
in with(Point2D) is trivially safe because of the instanceof

interface Point3D extends Point2D {
    int z(); Point3D withZ(int val);
    Point3D with(Point2D val); 
    // generated code
    Point3D withX(int val);
    Point3D withY(int val);
    public static Point3D of(int x, int y, int z){
        int x=_x; int y=_y; int z=_z;
        return new Point3D({
            public int x(){return x;}
            public int y(){return y;}
            public int z(){return z;}
            public Point3D withX(int val){
                return Point3D.of(val, this.y(), this.z());
            }
            public Point3D withY(int val){
                return Point3D.of(this.x(), val, this.z());
            }
            public Point3D withZ(int val){
                return Point3D.of(this.x(), this.y(), val);
            }
            public Point3D with(Point2D val){
                if(val instanceof Point3D)
                    return (Point3D)val;
                return Point3D.of(val.x(), val.y(), this.z());
            }
        });
    }
}

Figure 2. Generated boilerplate code.

test. The idea is that if the parameter is a subtype of the 
current exact type, then we can just return the parameter, as 
something that is just “more” than this.

Summary of operations in Classless Java In summary, ob-
ject interfaces provide support for different types of abstract 
state operations: four field-based state operations; and func-
tional updaters. Furthermore object interfaces support direct 
object instantiation via of factory methods. Figure 3 summar-
izes the six operations supported by @Obj. The field-based 
abstract state operations are determined by naming conven-
tions and the types of the methods. Fluent setters are a variant 
of conventional setters, and are discussed in more detail in 
Section 4.2.

2.5 Advanced Multiple Inheritance

Finally, defining Pegasus is as simple as we did in the simpli-
ﬁed (and stateless) version on the right of Figure 1. Note how 
even the non-trivial pattern for field type reﬁnement is trans-
parently composed, and Pegasus has a Point3D location.
@Obj interface Pegasus extends Horse, Bird {

3. Bridging between IB and CB in Java

Creating a new language/extension would be an elegant way 
to illustrate the point of IB. However, signiﬁcant amounts of 
engineering would be needed to build a practical language 
and achieve a similar level of integration and tool support as 
Java. To be practical, we have instead implemented @Obj as 
an annotation in Java 8, and a compilation agent. That is, the 
Classless Java style of programming is supported by library.

Disciplined use of Classless Java (avoiding class declara-
tions as done in Section 2) illustrates what pure IB is like.

### Figures

**Figure 3.** Abstract state operations for a field x, together with other operations, supported by the @0bj annotation.

**Figure 4.** The flow chart of @0bj annotation processing.

However, using @0bj, CB and IB programming can be mixed together, harvesting the practical convenience of using existing Java libraries, the full Java language, and IDE support. The key to our implementation is compilation agents, which allows us to rewrite the Java AST just before compilation. We discuss advantages and limitations of our approach.

#### 3.1 Compilation Agents

Java supports compilation agents, where Java libraries can interact with the Java compilation process, acting as a man in the middle between the generation of AST and bytecode.

This process is facilitated by frameworks like Lombok [27]: a Java library that aims at reducing Java boilerplate code via annotations. @0bj was created using Lombok. Figure 4 [14] illustrates the flow of the @0bj annotation. First Java source code is parsed into an abstract syntax tree (AST). The AST is then captured by Lombok: each annotated node is passed to the corresponding (Eclipse or Java) handler. The handler is free to modify the information of the annotated node, or even inject new nodes (like methods, inner classes, etc). Finally, the Java compiler works on the modified AST to generate bytecode.

**Advantages of Lombok** The Lombok compilation agent has advantages over pre-processors or other Java annotation processors. Lombok offers in Java an expressive power similar to that of Scala/Lisp macros, except, for the syntactic convenience of quote/unquote templating. Compilation agents act modularly on each compilation unit, applying transformations to one annotated class/interface at a time. This allows library code to be reused without the need of being reprocessed and recompiled, making our approach 100% compatible with existing Java libraries. In Eclipse, the processing is performed transparently and the information of the interface from compilation is captured in the “Outline” window as shown in Figure 5. This includes all the methods inside the interface as well as the generated ones.

#### 3.2 @0bj AST Reinterpretation

Of course, careless reinterpretation of the AST could still be surprising for badly designed rewritings. @0bj reinterprets the syntax with the sole goal of enhancing and completing code: we satisfy the behaviour of abstract methods; add method implementations; and refine return types. We consider this to be quite easy to follow and reason about, since it is similar to what happens in normal inheritance. Refactoring operations like renaming and moving should work transparently in conjunction with our annotation, since they rely on the overall type structure of the class, which we do not arbitrarily modify but just complete.

Thus, in addition to the advantages of Lombok, Classless Java offers some more advantages with respect to arbitrary (compilation agent driven) AST rewriting.

**Syntax and type errors** Some preprocessors (like the C one) can produce syntactically invalid code. Lombok ensures only syntactically valid code is produced. Classless Java additionally guarantees that no type errors are introduced in generated code and client code. We discuss these two guarantees in more detail next:

- **Self coherence:** the generated code itself is well-typed. That is, type errors are not present in code the user has not written (for example of methods in Figure 5). In our case, it means that either @0bj produces (in a controlled way) an understandable error or the interface can be successfully annotated and the generated code is well-typed.

- **Client coherence:** all the client code (for example method calls) that is well-typed before code generation is also well-typed after the generation. The annotation just adds more behaviour without removing any functionality.

**Heir coherence** Another form of guarantee that could be useful in AST rewriting is heir coherence. That is, interfaces (and in general classes) inheriting the instrumented code are well-typed if they were well-typed without the instrumentation. In a strict sense, our rewriting does not guarantee heir coherence. The reason is that this would forbid adding any (default or abstract) method to the annotated interfaces, or even doing type refinement. Indeed consider the following:

```java
interface A { int x(); A withX(int x); }
@0bj interface B extends A {}
interface C extends B { A withX(int x); }
```

This code is correct before the translation, but @0bj would generate in B a method "B withX(int x);". This would break C. Similarly, an expression of the form "new B(). A withX
Figure 5. Generated methods shown in the Outline window of Eclipse and auto-completion.

\[(\text{int } x)\{..\} \] would be correct before translation, but ill-typed after the translation.

Our automatic type refinement is a useful and convenient feature, but not transparent to the heirs of the annotated interface. They need to be aware of the annotation semantics and provide the right type while refining methods. To support heir coherence, we would need to give up automatic type refinement, which is an essential part of IB programming. However, the reader should note that Java libraries almost always break heir coherence during evolution and still claim backward compatibility (false in theory but statistically true in practice). In practice, adding any method to any non-final class of a Java library is enough to break heir coherence. We think return type refinement breaks heir coherence “less” than normal library evolution, and if no automatic type-refinements are needed, then \(@\)Obj can claim a form of heir coherence. We provide a formal definition for our safety claims here.

3.3 Limitations

Our prototype implementation has certain limitations:

- Lombok allows writing handlers for either javac or ejc (Eclipse’s own compiler). Our current implementation only realizes ejc version. The implementation for the javac version is still missing.
- Simple generics is supported: type parameters can be used, but generic method typing not explicitly checked by @Obj, but simply delegated to the Java compiler.
- Due to limited support in Lombok for separate compilation, i.e., accessing information of code defined in different files, @Obj requires that all related interfaces have to appear in a single Java file. Reusing the logic inside the experimental Lombok annotation @Delegate, we also offer a less polished annotation supporting separate compilation for files in the same package.

4. Applications and Case Studies

This section illustrates applications and larger case studies for Classless Java. The first application shows how a useful pattern, using multiple inheritance and type-refinement, can be conveniently encoded in Classless Java. The second application shows how to model embedded DSLs based on fluent APIs. The two larger case studies, take existing projects and refactor them into Classless Java. The first case study shows a significant reduction in code size, while the second case study maintains the same amount of code, but improves modularity.

4.1 The Expression Problem with Object Interfaces

As the first application for Classless Java, we illustrate a useful programming pattern that improves modularity and extensibility of programs. This useful pattern is based on an existing solution to the Expression Problem (EP) [22], which is a well-known problem about modular extensibility issues in software evolution. Recently, a new solution [23] using only covariant type refinement was proposed. When this solution is modeled with interfaces and default methods, it can even provide independent extensibility [25]: the ability to assemble a system from multiple, independently developed extensions. Unfortunately, the required instantiation code makes a plain Java solution verbose and cumbersome to use. The @Obj annotation is enough to remove the boilerplate code, making the presented approach very appealing. Our last case study, presented in Section 4.4, is essentially a (much larger) application of this pattern to an existing program. Here we illustrate the pattern in the much smaller Expression Problem.

Initial System

In the formulation of the EP, there is an initial system that models arithmetic expressions with only literals and addition, and an initial operation \(\text{eval}()\) for expression evaluation. As shown in Figure 6, \(\text{Exp}\) is the common super-interface with operation \(\text{eval}()\) inside. Sub-interfaces \(\text{Lit}\) and \(\text{Add}\) extend interface \(\text{Exp}\) with default implementations for the \(\text{eval}\) operation. The number field \(x\) of a literal is represented as a getter method \(x()\) and expression fields \((e1\) and \(e2)\) of an addition as getter methods \(e1()\) and \(e2()\).

Adding a New Type of Expressions

In the OO paradigm, it is easy to add new types of expressions. For example, the following code shows how to add subtraction.

\[
\begin{align*}
@\text{Obj} & \quad \text{interface} & & \text{Sub} & \text{extends} & \text{Exp} \\
& & \text{Exp} & e1(); & \text{Exp} & e2(); \\
& & \text{default int} & \text{eval}() & \{ & \text{return} e1().\text{eval}() - e2().\text{eval}(); & \}
\end{align*}
\]

Adding a New Operation

The difficulty of the EP in OO languages arises from adding new operations. For example, adding a pretty printing operation would typically change

---

3 See Section B
all existing code. However, a solution should add operations in a type-safe and modular way. This turns out to be easily achieved with the assistance of @Obj. The code in Figure 6 (on the right) shows how to add the new operation print. Interfaces ExpP extends Exp with the extra method print(). Interfaces LitP and AddP are defined with default implementations of print(), extending base interfaces Lit and Add, respectively. Importantly, note that in AddP, the types of “fields” (i.e. the getter methods) e1 and e2 are refined. If the types were not refined then the print() method in AddP would fail to type-check.

Independent Extensibility  To show that our approach supports independent extensibility, a new operation collectLit which collects all literal components in an expression is defined. For space reasons, we omit some code:

```
interface Exp { int eval(); }
@Obj interface Lit extends Exp {
  int x();
  default int eval() { return x();}
}
@Obj interface Add extends Exp {
  Exp e1(); Exp e2();
  default int eval() {
    return e1().eval() + e2().eval();
  }
}
```

Now we combine the two extensions together:

```
interface ExpPC extends Exp {
  List<Integer> collectLit();
}
@Obj interface LitC extends Lit, ExpPC {
  default int eval() { return x();}
}
@Obj interface AddC extends Add, ExpPC {
  Exp e1(); Exp e2();
  default int eval() {
    return e1().eval() + e2().eval();
  }
}
```

ExpPC is the new expression interface supporting print and collectLit operations; LitPC and AddPC are the extended variants. Notice that except for the routine of extends clauses, no glue code is required. Return types of e1,e2 must be refined to ExpPC.

Note that the code for instantiation is generated by @Obj. Creating a simple expression of type ExpPC is as simple as:

```
ExpPC e8 = AddPC.of(LitPC.of(3), LitPC.of(4));
```

Without our approach, tedious instantiation code would need to be defined manually.

4.2 Embedded DSLs with Fluent Interfaces

Since the style of fluent interfaces was invented in Smalltalk as method cascading, more and more languages (Java, C++, Scala, etc) came to support fluent interfaces. In most languages, to create fluent interfaces, programmers have to either hand-write everything or create a wrapper around the original non-fluent interfaces using this. In Java, there are several libraries (including jOOQ, op4j, flufl, JaQue, etc) providing useful fluent APIs. However most of them only provide a fixed set of predefined fluent interfaces.

The @Obj annotation can also be used to create fluent interfaces. When creating fluent interfaces with @Obj, there are two main advantages:

1. Instead of forcing programmers to hand-write code using
   return this, our approach with @Obj annotation removes this verbosity and automatically generates fluent setters.  
2. The approach supports extensibility: the return types of fluent setters are automatically refined.

We use embedded DSLs of two simple SQL query languages to illustrate. The first query language Database models select, from and where clauses:

```
@Obj interface Database {
  String select();
  Database from(String from);
  Database where(String where);
  static Database of() {
    return Database.of();
  }
}
```

The main benefit that fluent methods give us is the convenience of method chaining:

```
Database query1 = Database.of().select("a, b").from("Table").where("c > 10");
```

Note how all the logic for the fluent setters is automatically provided by the @Obj annotation.

Extending the Query Language  The previous query language can be extended with a new feature orderBy which orders the result records by a field that users specify. With @Obj programmers just need to extend the interface Database with new features, and the return type of fluent setters in Database is automatically refined to ExtendedDatabase:

```
@Obj interface ExtendedDatabase extends Database {
  String orderBy();
  ExtendedDatabase orderBy(String orderBy);
  static ExtendedDatabase of() {
    return Database.of();
  }
}
```

In this way, when a query is created using ExtendedDatabase, all the fluent setters return the correct type, and not the old Database type, which would prevent calling orderBy.

```
ExtendedDatabase query2 = ExtendedDatabase.of().
  select("a, b").from("Table").where("c > 10").
  orderBy("b");
```

4.3 A Maze Game

This case study is a simplified variant of a Maze game, which is often used [3, 9] to evaluate code reuse ability related to inheritance and design patterns. In the game, there is a player
with the goal of collecting as many coins as possible. She may enter a room with several doors to be chosen among. This is a good example because it involves code reuse (different kinds of doors inherit a common type, with different features and behavior), multiple inheritance (a special kind of door may require features from two other door types) and it also shows how to model operations symmetric sum, override and alias from trait-oriented programming. The game has been implemented using plain Java 8 and default methods by Bono et. al [3], and the code for that implementation is available online. We reimplemented the game using @obj. Due to space constraints, we omit the code here. The following table summarizes the number of lines of code and classes/interfaces in each implementation:

<table>
<thead>
<tr>
<th></th>
<th>SLOC</th>
<th># of classes/interfaces</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bono et al.</td>
<td>335</td>
<td>14</td>
</tr>
<tr>
<td>Ours</td>
<td>199</td>
<td>11</td>
</tr>
<tr>
<td>Reduced by</td>
<td>40.6%</td>
<td>21.4%</td>
</tr>
</tbody>
</table>

The @obj annotation allowed us to reduce the interfaces/classes used in Bono et al.’s implementation by 21.4% (from 14 to 11). The reductions were due to the replacement of instantiation classes with generated methods. The number of source lines of code (SLOC\(^5\)) was reduced by 40% due to both the removal of instantiation overhead and generation of getters/setters. To ensure a fair comparison, we used the same coding style as Bono et al.’s.

### 4.4 Refactoring an Interpreter

The last case study refactors the code from an interpreter for a Lisp-like language Mumbler\(^5\), which is created as a tutorial for the Truffle Framework [24]. Keeping a balance between simplicity and useful features, Mumbler contains numbers, booleans, lists (encoding function calls and special forms such as if-expression, lambdas, etc). In the original code base, which consists of 626 SLOC of Java, only one operation `eval` is supported. Extending Mumbler to support one more operation, such as a pretty printer `print`, would normally require changing the existing code base directly.

Our refactoring applies the pattern presented in Section 4.1 to the existing Mumbler code base to improve its modularity and extensibility. Using the refactored code base it becomes possible to add new operations modularly, and to support independent extensibility. We add one more operation `print` to both the original and the refactored code base. In the original code base the pretty printer is added non-modularly by modifying the existing code. In the refactored code base the pretty printer is added modularly. Although the code in the refactored version is slightly increased (by 2.4% SLOC), the modularity is greatly increased, allowing for improved reusability and maintainability. We list the results in the following table:

<table>
<thead>
<tr>
<th></th>
<th>SLOC</th>
<th>Code</th>
<th>SLOC</th>
</tr>
</thead>
<tbody>
<tr>
<td>original (eval)</td>
<td>626</td>
<td>original (eval+print)</td>
<td>661</td>
</tr>
<tr>
<td>refactored (eval)</td>
<td>560</td>
<td>refactored (eval+print)</td>
<td>677</td>
</tr>
</tbody>
</table>

### 5. Related Work

#### Multiple inheritance in object-oriented languages

Many authors have argued in favor or against multiple inheritance. Multiple implementation inheritance is very expressive, but difficult to model and implement, and can cause difficulties (including the famous diamond (fork-join) problem [4, 18], conflicting methods, etc.) in reasoning about programs. To conciliate the need for expressive power and simplicity, many models have been proposed, including C++ virtual inheritance, mixins [4], traits [19], and hybrid models such as CZ [13]. They provide novel programming architecture models in the OO paradigm. In terms of restrictions set on these models, C++ virtual inheritance aims at a relative general model; the mixin model adds some restrictions; and the trait model is the most restricted one (excluding state, instantiation, etc).

C++ has a general solution to multiple inheritance by virtual inheritance, dealing with the diamond problem by keeping only one copy of the base class [7]. However C++ suffers from the object initialization problem [13]. It bypasses constructor calls to virtual superclasses, which can cause serious semantic errors. In our approach, the @obj annotation has full control over object initialization, and the mechanism is transparent to users. Moreover, customized factory methods are also allowed: if users are not satisfied with the default generated of method, they can implement their own.

Mixins are more restricted than the C++ approach. Mixins allow naming components that can be applied to various classes as reusable functionality units. However, the linearization (total ordering) of mixin inheritance cannot provide a satisfactory resolution in some cases and restricts the flexibility of mixin composition. To fight this limitation, an algebra of mixin operators is introduced [1], but this raises the complexity, especially when constructors and fields are considered [26]. Scala traits [15] are in fact more like linearized mixins. Scala avoids the object initialization problem by disallowing constructor parameters, causing no ambiguity in cases such as the diamond problem. However this approach has limited expressiveness, and suffers from all the problems of linearized mixin composition. Java interfaces and default methods do not use linearization: the semantics of Java `extends` clause in interfaces is unordered and symmetric.

Malayeri and Aldrich proposed a model CZ [13] which allows to do multiple inheritance without the diamond problem. Inheritance is divided into two concepts: inheritance dependency and implementation inheritance. Using a combination of `requires` and `extends`, a program with diamond inheritance is transformed to one without diamonds. Moreover, fields and multiple inheritance can coexist. However untangling inheritance also untangles the class structure. In CZ, not only the number of classes, but also the class hierarchy

\(^5\) Only Java code is counted, excluding comments and blank lines.

\(^3\) https://github.com/cesquis/mbml/tree/master/simple
complexity increases. IB does not complicate the hierarchical structure, and state also coexists with multiple inheritance.

Simplifying the mixins approach, traits [19] draw a strong line between units of reuse and object factories. Traits, as units of reusable code, contain only methods as reusable functionality, ignoring state and state initialization. Classes, as object factories, require functionality from (multiple) traits. Java 8 interfaces are closely related to traits: concrete method implementations are allowed (via the default keyword) inside interfaces. The introduction of default methods opens the gate for various flavors of multiple inheritance in Java. Traits offer an algebra of composition operations like sum, alias, and exclusion, providing explicit conflict resolution. Former work [3] provides details on mimicking the trait algebra through Java 8 interfaces.

There are also proposals for extending Java with traits. For example, FeatherTrait Java (FTJ) [12] extends FJ [11] with statically-typed traits, adding trait-based inheritance in Java. Except for few, mostly syntactic details, their work can be emulated with Java 8 interfaces. There are also extensions to the original trait model, with operations (e.g. renaming [16], which breaks structural subtyping) that default methods and interfaces cannot model.

**Traits vs Object Interfaces.** We consider object interfaces to be an alternative to traits or mixins. In the trait model two concepts (traits and classes) coexist and cooperate. Some authors [2] see this as good language design fostering good software development by helping programmers to think about the structure of their programs. However, other authors see the need of two concepts and the absence of state as drawbacks of this model [13]. Object interfaces are units of reuse, and at the same time they provide factory methods for instantiation and support state. Our approach promotes the use of interfaces instead of classes, in order to rely on the modular composition offered by interfaces. Since Java was designed for classes, a direct classless programming style is verbose and unnatural. However, annotation-driven code generation is enough to overcome this difficulty, and the resulting programming style encourages modularity, composability and reusability, by keeping a strong OO feel. In that sense, we promote object interfaces as being both units of reusable code and object factories. Our practical experience is that, in Java, separating the two notions leads to a lot of boilerplate code, and is quite limiting when multiple inheritance with state is required. Abstract state operations avoid the key difficulties associated with multiple inheritance and state, while still being quite expressive. Moreover the ability to support constructors adds expressivity, which is not available in approaches such as Scala’s traits/mixins.

**ThisType and MyType** Object interfaces support automatic type-refinement. Type refinement is part of a bigger topic in class-based languages: expressing and preserving type recursion and (nominal/structural) subtyping at the same time. One famous attempt in this direction is provided by My-

Type [5], representing the type of this, changing its meaning along with inheritance. However when invoking a method with MyType in a parameter position, the exact type of the receiver must be known. This is a big limitation in class-based object-oriented programming, and is exasperated by the interface-based programming we propose: no type is ever going to be exact since classes are not explicitly used. A recent article [17] lights up this topic, proposing two new features: exact statements and noninheritable methods. Both are related to our work: 1) any method generated inside the of method is indeed non-inheritable since there is no class name to extend from; 2) exact statements (a form of wildcard capture on the exact run-time type) could capture the “exact type” of an object even in a class-less environment. Admittedly, MyType greatly enhances the expressiveness and extensibility of object-oriented programming languages. Object interfaces use covariant-return types to simulate some uses of MyType. But this approach only works for refining return types, whereas MyType is more general, as it also works for parameter types. Our approach to covariantly refine state can recover some of the additional expressiveness of MyType.

As illustrated with our examples and case studies, object interfaces are still very useful in many practical applications, yet they do not require additional complexity from the type system.

6. Conclusion

Before Java 8, concrete methods and static methods were not allowed to appear in interfaces. Java 8 allows static interface methods and introduces default methods, which enables implementations inside interfaces. This had an important positive consequence that was probably overlooked: the concept of class (in Java) is now (almost) redundant and unneeded. We proposed a programming style, called Classless Java, where truly object-oriented programs and (reusable) libraries can be defined and used without ever defining a single class.

However, using this programming style directly in Java is very verbose. To avoid syntactic boilerplate caused by Java not being originally designed to work without classes, we introduce a new annotation, @Obj, which provides default implementations for various methods (e.g. getters, setters, with-methods) and a mechanism to instantiate objects. We leverage on annotation processing and the Lombok library, in this way @Obj is just a normal Java library; thus our proposed style can be integrated in any Java project. The @Obj annotation helps programmers to write less cumbersome code while coding in Classless Java. Indeed, we think the obtained gain is so high that Classless Java with the @Obj annotation can be less cumbersome than full Java.

Classless Java is just a programming style, but is showing the way for a new flavour of object orientation: We propose interface-based object-oriented languages (IB), as opposed to class-based or prototype-based. In IB state is not modelled at the platonic/ideal level but is handled exclusively by instances.
This unlocks useful code reuse patterns, as shown in Section 2. An interesting avenue for future work would be to design a new language based on IB. With a proper language design we would not need to restrict ourselves to the limitations of Java and its syntax.
References

A. Formal Semantics

This section presents a formalization of Classless Java, which models the essence of Java interfaces with default methods. This formalization is used to define the semantics of object interfaces.

A.1 Syntax

Figure 7 shows the syntax of Classless Java. The syntax formalizes a minimal subset of Java 8, focusing on interfaces, default methods and object creation literals. There is no syntax for classes. To help readability we use many metavariables to represent identifiers: C, x, f and m; however they all map to a single set of identifiers as in Java. Expressions consist of conventional constructs such as variables (x), method calls (e.m(σ)) and static method calls (I.m(σ)). For simplicity the degenerate case of calling a static method over the this receiver is not considered. A more interesting type of expressions is super calls (I.super.m(σ)), whose semantics is to call the (non-static) method m over the this receiver, but statically dispatching to the version of the method as visible in the interface I. A simple form of field updates (x=e;e′) is also modeled. In the syntax of field updates x is expected to be a field name. After updating the field x using the value of e, the expression e′ is executed. To blend the statement based nature of Java and the expression based nature of our language, we consider a method body of the form return x=e;e′ to represent x=e;return e′ in Java. Finally, there is an object initialization expression from an interface I, where (for simplicity) all the fields are initialized with a variable present in scope. To be fully compatible with Java, the concrete syntax for an interface declaration with empty supertype list would also omit the extends keyword. Following standard practice, we consider a global Interface Table (IT) mapping from interface names I to interface declarations I.

The environment Γ is a mapping from variables to types. As usual, we allow a functional notation for Γ to do variable lookup. Moreover, to help us define auxiliary functions, a functional notation is also allowed for a set of methods meth, using the method name m as a key. That is, we define meth(m) = meth iff there is a unique meth ∈ meth whose name is m. For convenience, we define meth(m) = None otherwise; moreover m ∈ dom(meth) iff meth(m) = meth. For simplicity, we do not model overloading, thus for an interface to be well formed its methods must be uniquely identified by their names.

A.2 Typing

Typing statement Γ ⊨ e ∈ I reads “in the environment Γ, expression e has type I.”. Before discussing the typing rules we discuss some of the used notation. As a shortcut, we write Γ ⊨ e ∈ I instead of Γ ⊨ e ∈ I and I ⊨ e.

We omit the definition of the usual traditional subtyping relation between interfaces, that is the transitive and reflexive closure of the declared extends relation. The auxiliary notation Γ^{mth} trivially extracts the environment from a method header, by collecting the all types and names of the method parameters. The notation m^{meth} and I^{meth} denote respectively, extracting the method name and the return type from a method header. mbod(m, I), defined in Appendix A.3, returns the full method declaration as seen by I, that is the method m can be declared in l or inherited from another interface. mtype(m, I) and mtypeS(m, I) return the type signature from a method (using mbod(m, I) internally). mtype(m, I) is defined only for non static methods, while mtypeS(m, I) only for static ones. We use dom(I) to denote the set of methods that are defined for type I, that is: m ∈ dom(I) iff mbod(m, I) = meth.

In Figure 8 we show the typing rules. We discuss the most interesting rules, that is (T-OBJ) and (T-INT). Rule (T-OBJ) is the most complex typing rule. Firstly, we need to ensure that all field initializations are type correct, by looking up the type of each variable assigned to a field in the typing environment and verifying that such type is a subtype of the field type. Finally, we check that all method bodies are well-typed. To do this the environment used to check the method body needs to be extended appropriately: we add all fields and their types; add this : I; and add the arguments (and types) of the respective method. Now we need to check if the object is a valid extension for that specific interface. This can be logically divided into two steps. First we check that all method headers are valid with respect to the corresponding method already present in I:

- sigvalid(mh_1 . . . mh_n, I) = \forall i ∈ 1..n mh_i ; < : mbod(m^{meth_i}, I)

Here we require that for all newly declared methods, there is a method with the same name defined in the interface I, and that such method is a supertype of the newly introduced one. We define subtyping between methods in a general form that will also be useful later.

- I m(I_1x_1 . . . I_nx_n) ; < : I(m(I_1x'_1 . . . I_nx'_n)) = I ; L
- meth < : default mh(return ;) = meth < : mh;
- default mh(return ;) < : meth = mh; < : meth

We allow return type specialization as introduced in Java 5. A method header with return type I is a subtype of another method header with return type I’ if all parameter types are the same, and I <: I’. A default method meth_1 is a subtype of another default method meth_2 iff m^{meth_1} is a subtype of m^{meth_2}. Secondly, we check that all abstract methods (which need to be explicitly overridden) in the interface have been implemented:

- alldefined(mh_1 . . . mh_n, I) = \forall m such that mbod(m, I) = mh; \exists i ∈ 1..n m^{meth_i} = m

The rule (T-INT) checks that an interface type is correctly typed. First we check that the body of all default and static methods are well-typed. Then we check that dom(I) is the same as dom(I_1) ∪ . . . ∪ dom(I_n) ∪ dom(meth). This is not a trivial check, since dom(I) is defined using mbod, which would be undefined in many cases: notably if a method meth ∈ meth is not compatible with some method in
dom($I_1$) \ldots dom($I_n$) or if there are methods in any dom($I_i$) and dom($I_j$) (i, j ∈ 1..n) conflict.

A.3 Auxiliary Definitions

Defining mbody is not trivial, and requires quite a lot of attention to the specific model of Java interfaces, and to how it differs w.r.t. Java Class model. mbody($m, I$) denotes the actual method $m$ (body included) that interface $I$ owns. The method can either be defined originally in $I$ or in its superinterfaces, and then passed to $I$ via inheritance.

- $\text{mbody}(m, I_0) = \text{override}(\text{meth}(m), \text{needed}(m, I))$ with $\text{IT}(I_0) = \text{ann interface } I_0 \text{ extends } I_1 \ldots I_n (\text{meth})$ and $I \in \mathcal{I}$ if $i \not<: I, i \in 1..n$

The definition of mbody reconstructs the full set of supertypes $I$ and then delegates the work to two other auxiliary functions: needed($m, I$) and override($\text{meth}, \text{meth}$).

needed recovers from the interface table only the “needed” methods, that is, the non-static ones that are not reachable by another, less specific superinterface. Since the second parameter of needed is a set, we can choose an arbitrary element to be $I_0$. In the definition we denote by originalMethod($m, I_0$) = meth the non-static method called $m$ defined directly in $I$. Formally:

- originalMethod($m, I_0$) = meth with $\text{IT}(I_0) = \text{ann interface } I_0 \text{ extends } I (\text{meth})$, meth ∈ meth not static, $m = \text{meth}$
- originalMethod($m, I_0$) ∈ needed($m, I_0 \ldots I_n$) = $\exists i \in 1..n$ such that originalMethod($m, I_i$) is defined and $I_i \not<: I_0$

override models how a method in an interface can override implementations in its superinterfaces, even in the case of conflicts. Note how the special value None is used, and how (the 5th case) overriding can solve a conflict.

- override(None, $\emptyset$) = None
- override($\text{meth}, \emptyset$) = $\text{meth}$
- override(None, $\text{meth}$) = $\text{meth}$
- override(None, $\text{meth}$) = mostSpecific($\text{meth}$)
- override($\text{meth}, \text{meth}'$) = $\text{meth}$ with $\forall \text{meth}' \in \text{meth} : \text{meth} \not<: \text{meth}'$

The definition mostSpecific returns the most specific method whose type is the subtype of all the others. Since method subtyping is a partial ordering, mostSpecific may not be defined, this in turn forces us to rely on the last clause of override; otherwise the whole mbody would not be defined for that specific $m$. Rule (T-INTF) relies on this behavior.
mostSpecific(meth) = meth
    with meth ∈ meth and ∀meth′ ∈ meth : meth < meth′

To illustrate the mechanism of mbody, we present an example. We compute mbody(m,D):

```java
interface A { Object m(); }
interface B extends A { default Object m() { return this.m(); } }
interface C extends A {
    interface D extends B, C { String m(); }
}
```

- First \{A,B,C\}, the full set of supertypes of D is obtained.
- Then we compute needed(m, \{A,B,C\}) = default Object m()\{\ldots\}, that is B.m. That is, we do not consider either C.m (since m is not declared directly in C, hence originalMethod(m,c) is undefined) or B.m (that is a subtype of A, thus B.m hides A.m).
- The final step computes override(D.m,B.m) = D.m, by the last case of override we get that D.m hides B.m successfully (String is a subtype of Object). Finally we get mbody(m,D) = D.m.

### B. What @Obj Generates

This section gives an overview of what @Obj generates, and what formal properties are guaranteed in the translation.

We formalize syntax and typing for Classless Java in Appendix A, which models the essence of Java interfaces with default methods. Classless Java is just a proper subset of Java 8, so it is easy to understand the translation presented in this section without the syntax and typing rules of Classless Java. Since the formalized part of Classless Java does not consider casts or instanceof, the with method is not included in the formal translation. For the same reason void returning setters are not included, since they are just a minor variation over the more interesting fluent setters and they would require special handling just for the conventional void type. Since our properties are about preserving typing, we do not need to formalize Classless Java semantics to prove our statements.

#### B.1 Translation

For the purposes of the formalization, the translation is divided into two parts for more convenient discussion on formal properties later. To this aim we introduce the annotation @Obj. Its role is only in the translation process, hence it is not part of the Classless Java language. @Obj generates the constructor method of, while @Obj automatically refines the return types and calls @Obj.

Figure 9 presents the translation. In the first function, @Obj injects refined methods to interface I0. The second function, @Obj invokes ofMethod(I0) and generates the of method for I0, if such a method does not exist in its domain, and all the abstract methods are valid for the annotation.

Figure 10 presents more details on the auxiliary functions. The first two points of Figure 10 define function refine. This function generates unimplemented with- and fluent setters in the interface, where the return types have been refined. To determine whether a method needs to be generated, we check if such with- or setter methods require an implementation in I0, but are not declared directly in I0. The third point gives the definition of valid: it is valid to annotate an interface if all abstract methods (that is, all those requiring an implementation) are valid. That is, we can categorize them in a pattern that we know how to implement (right column): it is either a field getter (first point), a with method (second point) or a setter (third point). Note that we write with#m to append m to with, following the camelCase rule. The first letter of m must be lower-case and is changed to upper-case upon appending. For example with#foo=withFoo. Special names special(m) are with and all identifiers of the form with#m.

Since the formalized part of Classless Java does not depend on Java 8, so it is easy to understand the translation presented in this section. Furthermore, we can show that if there are no type-refinements, then heir coherence also holds. The result about heir coherence is possible to prove because the translation is split into two parts. In essence heir coherence is a property of the translation of @Obj, but not of @Obj.

To formally characterize the behavior of our annotation and the two levels of guarantees that we offer, we provide some notations and two theorems:

- We denote I and m\text{meth} the name of an interface and of a method.
- An interface table IT is OK if under such interface table, all interfaces are OK, that is, well typed.
- Since interface tables are just represented as sequences of interfaces we write IT = IT′ to select a specific interface in a table.
- IT contains an heir of I if there is an interface that extends it, or a new that instantiates it.

**Theorem 1** (@ObjOf). If a given interface table \(\cal I\) IT is OK where \(\cal I\) has @ObjOf, valid(I′) and of ∉ dom(I′), then the interface table \([\cal I]\) IT is OK.

**Theorem 2** (@Obj). If a given interface table \(\cal I\) IT is OK where \(\cal I\) has @Obj, valid(I′) and of ∉ dom(I′), and there is no heir of I′, then the interface table \([\cal I]\) IT is OK.

\textbf{C. What @obj Generates}

This section presents a formal definition for most of the generated methods by @obj.

\textbf{C.1 Translation}

The translation functions of @obj and @obj of are presented in Figure 9. Note that it is necessary to explicitly check if the interface is valid for annotation:

- valid(I_0) = \forall m \in \text{dom}(I_0), \text{if } mh; = \text{mbody}(m, I_0),
  one of the following cases is satisfied:
  - isField(\text{meth}), isWith(\text{meth}, I_0) or isSetter(\text{meth}, I_0)
  - isField(I m()); = \not \text{special}(m)
  - isWith(I' with\#(I x);, I_0) =\)
  - \( I_0 <; I', \text{mbody}(m, I_0) = I m(); \text{ and not special}(m)
  - isSetter(I' \_m(I x);, I_0) =\)
  - \( I_0 <; I', \text{mbody}(m, I_0) = I m(); \text{ and not special}(m)

That is, we can categorize all abstract methods in a pattern that we know how to implement: it is either a field getter, a with method or a setter.

Moreover, we check that the method of is not already defined by the user. In the formalization an existing definition of the of method is an error. However, in the prototype (which also needs to account for overloading), the check is more complex as it just checks that an of method with the same signature of the one being generated is not already present.

We write with\# to append m to with, following the camelCase rule. The first letter of m must be lower-case.
and is changed to upper-case upon appending. For example 

\texttt{with\#foo=withFoo}. Special names \texttt{special(m)} are with-

\texttt{and} all identifiers of the form \texttt{with\#m}.

The \texttt{refine} function: \texttt{refine(I0, meth)} is defined as follows:

\begin{itemize}
  \item \texttt{I0 with\#m(I.val); \in refine(I0, meth) =}
  \texttt{isWith(mbody(with\#m, I0), I0, with\#m \notin dom(meth))}
  \item \texttt{I0.m(I.val); \in refine(I0, meth) =}
  \texttt{isSetter(mbody(_m, I0), I0) . \_m \notin dom(meth)}
\end{itemize}

The methods generated in the interface are \texttt{with-}

\texttt{and setters. The methods are generated when they are unimplemented in
I0, because the return types need to be refined. To determine whether the
methods need to be generated, we check if such
with- or setter methods are required by \texttt{I0}, but not declared
directly in \texttt{I0}.

The \texttt{ofMethod} function: The function \texttt{ofMethod} generates the
method \texttt{of}, as an object factory. To avoid boring
digressions into well-known ways to find unique names, we
assume that all methods with no parameters do not start with an underscore, and we prefix method names
with underscores to obtain valid parameter names for \texttt{of}.

\begin{itemize}
  \item \texttt{ofMethod(I0) = static I0 of(I1..m1, ..., In..mn) {}
    return new I0();
    I1 m1 = _m1; ... In mn = _mn;
    I1 m1 {return m1;} ... In mn {return mn;}
    withMethod(I1, m1, I0, \_i) ... withMethod(In, mn, I0, \_n)
    setterMethod(I1, m1, I0) ... setterMethod(In, mn, I0)
  }
  \item with I1 m1; ... In mn = fields(I0)
  \item and \_i = m1, ..., _i-1, _val, _i+1, ..., _in
\end{itemize}

Note that, the function \texttt{fields(I0)} denotes all the fields in the
current interface:

\texttt{meth \in fields(I0) =}
\texttt{isField(meth) and meth = mbody(m\_meth, I0)}

For methods inside the interface with the form \texttt{I, m1;}

\begin{itemize}
  \item \texttt{m} is the field name, and has type \texttt{I}.
  \item \texttt{m1} is the getter and just returns the current field value.
  \item if a method \texttt{with\#m1} is required, then it is implemented
    by calling the \texttt{of} method using the current value for all
    the fields except for \texttt{m1}. Such new value is provided as a
    parameter. This corresponds to the expressions \texttt{\_i}.
  \item \texttt{\_m1(I.val)} is the setter. In our prototype we name
    \texttt{m1}, here we use the underscore to avoid modeling over-
    loading.
\end{itemize}

The auxiliary functions are defined below. Note that we
do not need to check if some header is a subtype of what we
would generate, this is ensured by \texttt{valid(I0)}.

\begin{itemize}
  \item \texttt{withMethod(I, m, I0, \_i) =}
    \texttt{I0 with\#m(I.val) {return I0.of(\_i);}}
    \texttt{mbody(with\#m, I0) having the form \texttt{mh};}
  \item \texttt{withMethod(I, m, I0, \_i) =}
    \texttt{\_m(I.val) {\_m= \_val; return this;}}
    \texttt{mbody(\_m, I0) having the form \texttt{mh;}}
  \item \texttt{setterMethod(I, m, I0) =}
    \texttt{\_m(I.val) = \_null otherwise}
\end{itemize}

C.2 Other Features

We do not formally model non-fluent setters and the \texttt{with}
method. An informal explanation of how those methods are
generated is given next:

\begin{itemize}
  \item For methods inside the interface with the form \texttt{void
    m(I.x);}
    \texttt{Check if method I m(); exists. If not, generate error
    (that is, valid(I0) is false).}
    \texttt{Generate the implemented setter method inside of:}
    \texttt{public void m(I .val){ \_m= \_val;}}
    \texttt{There is no need to refine the return type for non-fluent
    setters, thus we do not need to generate the method
    header in the interface body itself.}
  \item For methods with the form I \texttt{\_with}(I x);
    \texttt{I must be an interface type (no classes or primitive types)}.
    \texttt{As before, check that I is a supertype of the current
    interface type I0.}
    \texttt{Generate implemented \texttt{with} method inside of:}
    \texttt{public I0 with(I.val){}
      if(\_val instanceof I0){ return (I0) .val;}
      return I0.of(e1...en);}
    \texttt{with \_e1= \_val.m1 if I has a \_m1 method where
    m1...mn are fields of I0; otherwise \_e1 = \_m1.}
    \texttt{If needed, as for \texttt{with-} and setters, generate the method
    headers with refined return types in the interface.}
\end{itemize}

D. Lemmas and Theorems

D.1 \texttt{LEMMA 1} and Proof

\textbf{Lemma 1} (a). \textit{For any expression \(e\) under an interface table \(I IT\) where \(\Gamma \vdash e \in I^2\), \(I\) has \#obj\_of annotation and \([I] = \mathcal{I}'\), then under the interface table \(I' IT, \Gamma \vdash e \in I^2\).}

\textit{Proof.} By induction on the typing rules: by the grammar
shown in Figure 7, there are 6 cases for an arbitrary expression \(e\):

\begin{itemize}
  \item Variables are typed in the same exact way.
  \item Field update. The type preservation is ensured by induc-
    tion.
  \item A method call (normal, static or super). The corresponding
    method declaration won’t be “removed” by the translation, also
    the types remain unchanged. The only work \#obj\_of does is adding
    a static method \# of to the interface, however, a pre-condition
    of the translation is \# of \(\notin dom(I^2)\), so adding \# of method
    has no way to affect any formerly well typed method call.
  \item An object creation. Adding the \# of method doesn’t intro-
    duce unimplemented methods to an interface, moreover, the
    static method is not inheritable, hence after translation
    such an object creation still type checks and has the right
    type by induction.
\end{itemize}
Lemma 1 (b). For any expression \( e \) under an interface table \( I \) \( IT \) where there is no heir of \( I \), \( \Gamma \vdash e \in I^T \), \( I \) has @obj annotation and \( [I] = I' \), then under the interface table \( I' \) \( IT \), \( \Gamma \vdash e \in _{-} : I^T \).

Proof. The proof follows the same scheme of Lemma 1 (a), but for the case of method call the return type may be refined with a subtype. This is still ok since we require \( _{-} : I^T \). On the other side, this weaker result still allows the application on the method call typing rules, since in the premises the types of the actual parameter are required to be a subtype of the formal one.

\[ \square \]

D.2 LEMMA 2 and Proof

Lemma 2 (a). If \( I \) has @obj of annotation and \( I^T \) OK in \( I IT \), then \([I] \) OK in \([I] IT \).

Proof. By the rule (T-INTF) in Figure 8, we divide the proof into two parts.

Part 1. For each default or static method in the domain of \([I^T] \), the type of the return value is compatible with the method's return type.

Since \( I \) OK, and by Lemma 1 (a), all the existing default and static methods are well typed in \([I] \), except for the new method \( of \). It suffices to prove that it still holds for \( ofMethod(I) \).

By the definition of \( ofMethod(I) \), the return value is an object

\[ \text{return new } I^T() \{ \ldots \} \]

To prove it is of type \( I^T \), we use the typing rule (T-OBJ).

- All field initializations are type correct. By the definition of \( ofMethod(I^T) \) in Appendix C.1, the fields \( m_1, \ldots, m_n \), are initialized by \( of \)’s arguments, and types are compatible.
- All method bodies are well-typed.
  - Typing of the \( i \)-th getter \( m_i \).\n    \[ \Gamma, m_i : I_i, this : I^T \vdash m_i \in I_i \]
    We know that \( I_i = I^T \) since the \( i \)-th getter has its return type the same as the corresponding field \( m_i \).\n  - Typing of the \( with \)- method of an arbitrary field \( m_i \).\n    By Appendix C.1, if the \( with \)- method of \( m_i \) is well-defined, it has the form
    \[ I^T with\#m_i(I_i \_val)\{ return I^T.of(\tau_i) ; \} \]
    \( \tau_i \) is obtained by replacing \( m_i \) with \( \_val \) in the list of fields, and since they have the same type \( I_i \), the arguments \( \tau_i \) are compatible with \( I^T.of \) method. Hence
    \[ \Gamma, m_1 : I_1 \ldots m_n : I_n, this : I^T, \_val : I_i \vdash I^T.of(\tau_i) \in I^T \]
    We know that \( I^T = I^T \) by the return type of \( with\#m_i \), shown as above.
  - Typing of the \( i \)-th setter \( _m_i \).\n    If the \( _m_i \) method is well-defined, it has the form
    \[ I^T \_m_i(I_i \_val)\{ m_i = \_val; return this; \} \]
    By (T-UPDATE), the assignment \( "m_i = \_val;" \) is correct since \( m_i \) and \( \_val \) have the same type \( I_i \), and the return type is decided by \( this \).
    \[ \Gamma, this : I^T, \_val : I_i \vdash this \in I^T \]
    We know that \( I^T = I^T \) by the return type of \( _m_i \) shown as above.
- All method headers are valid with respect to the domain of \( I^T \). Namely
    \[ \text{sigvalid}(mh_1 \ldots mh_n, I) \]
    For convenience, we use "\( \text{meth} \) in \( \text{ofMethod}(I^T) \)" to denote that \( \text{meth} \) is one of the implemented methods in the return expression of \( \text{ofMethod}(I^T) \), namely \( \text{new } I^T() \{ \ldots \} \).
  - For the \( i \)-th getter \( m_i \),
    \[ I, m_i() \{ \ldots \} \text{ in } \text{ofMethod}(I^T) \]
    implies \( I, m_i(); \in \text{fields}(I^T) \)
    implies \( I, m_i(); = \text{mbody}(m_i, I^T) \)
    implies \( I, m_i(); : <: \text{mbody}(m_i, I^T) \)
  - For the \( \text{with}\#m_i \) method,
    \[ I^T with\#m_i(I_i \_val)\{ \ldots \} \text{ in } \text{ofMethod}(I^T) \]
    implies \( \text{mbody}(\text{with}\#m_i, I^T) \) is of form \( mh \);
    with \( \text{valid}(I^T) \)
    implies \( \text{isWith}(\text{mbody}(\text{with}\#m_i, I^T), I^T) \)
    implies \( I^T with\#m_i(I_i \_val) ; : <: \text{mbody}(\text{with}\#m_i, I^T) \)
  - For the \( i \)-th setter \( _m_i \),
    \[ I^T \_m_i(I_i \_val)\{ \ldots \} \text{ in } \text{ofMethod}(I^T) \]
    implies \( \text{mbody}(\_m_i, I^T) \) is of form \( mh \);
    with \( \text{valid}(I^T) \)
    implies \( \text{isSetter}(\text{mbody}(\_m_i, I^T), I^T) \)
    implies \( I^T \_m_i(I_i \_val) ; : <: \text{mbody}(\_m_i, I^T) \)
  - All abstract methods in the domain of \( I^T \) have been implemented. Namely
    \[ \text{aligned}(mh_1 \ldots mh_n, I) \]
    Here we simply refer to \( \text{valid}(I^T) \), since it guarantees each abstract method to satisfy isField, isWith or isSetter. But that object includes all implementations for those cases. A getter \( m_i \) is generated if it satisfies isField; a \( \text{with} \)-method is generated for the case isWith, by the definition of \( \text{withMethod} \); a setter for isSetter, similarly, by the definition of setMethod. Hence it is of type \( I^T \) by (T-OBJ).
Part II. Next we check that in \( \{I\} \),
\[
\text{dom}(\{I\}) = \text{dom}(I_1) \cup \ldots \cup \text{dom}(I_n) \cup \text{dom}(\text{meth}) \cup \text{dom}(\text{meth}')
\]
Since \( \mathcal{I} \) OK, we have \( \text{dom}(\mathcal{I}) = \text{dom}(I_1) \cup \ldots \cup \text{dom}(I_n) \cup \text{dom}(\text{meth}) \), and hence it is equivalent to prove
\[
\text{dom}(\{I\}) = \text{dom}(I^2) \cup \text{dom}(\text{meth}')
\]
This is obvious since a pre-condition of the translation is \( \text{of} \notin \text{dom}(I^2) \), so \( \text{meth}' \) doesn’t overlap with \( \text{dom}(I^2) \). The definition of \( \text{dom} \) is based on \( \text{mbody} \), and here the new domain \( \text{dom}(\{I\}) \) is only an extension to \( \text{dom}(I) \) with the \( \text{of} \) method, namely \( \text{meth}' \). Also note that after translation, there are still no methods with conflicted names, since the \( \text{of} \) method was previously not in the domain, hence \( \{I\} \) is well-formed, which finishes our proof.

Lemma 2 (b). If \( \mathcal{I} \) has \( \text{@Obj} \) annotation \( I^2 \) OK in \( \mathcal{I} \) IT and there is no heir of \( I \), then \( \{I\} \) OK in \( \{I\} \) IT.

Proof. Part I. Similarly to what already argued for Lemma 2 (a), since \( \mathcal{I} \) OK, and by Lemma 1 (b), all the existing default and static methods are well typed in \( \{I\} \) IT. The translation function delegates its work to \( \text{@ObjOf} \) in such way that we can refer to Lemma 2 (a) to complete this part. Note that all the methods added (directly) by \( \text{@Obj} \) are abstract, and thus there is no body to typecheck.

Part II. Similar to what we already argued for Lemma 2 (a), but we need to notice that the newly added methods are valid refinements for already present methods in \( \text{dom}(I^2) \) before the translation. Thus by the last clause of the definition of \( \text{override}(\_\_\_) \), \( \text{mbody}(\_\_) \) is defined on the same method names.

D.3 THEOREM and Proof

Theorem 1 (@ObjOf tuning). If a given interface table \( \mathcal{I} \) IT is OK where \( \mathcal{I} \) has \( \text{@ObjOf} \), valid \( (I^2) \) and \( \text{of} \notin \text{dom}(I^2) \), then the interface table \( \{I\} \) IT is OK.

Proof. Lemma 2 (a) already proves that \( \{I\} \) is OK. On the other hand, for any \( \mathcal{I}' \in \text{IT}\setminus\mathcal{I} \), by Lemma 1 (a), we know that all its methods are still well-typed, and the generated code in translation of \( \text{@ObjOf} \) is only a static method \( \text{of} \), which has no way to affect the domain of \( \mathcal{I}' \), so after translation rule \( \text{(T-INF)\_OF} \) can still be applied, which finishes our proof.

Theorem 2 (@Obj tuning). If a given interface table \( \mathcal{I} \) IT is OK where \( \mathcal{I} \) has \( \text{@Obj} \), valid \( (I^2) \) and \( \text{of} \notin \text{dom}(I^2) \), and there is no heir of \( I^2 \), then the interface table \( \{I\} \) IT is OK.

Proof. Similar to what already argued for Theorem 1, we can apply Lemma 2 (b) and Lemma 1 (b). Then we finish by Theorem 1.
